

Singleturn absolute encoder

ASS58-0

- Industrial standard housing Ø58 mm
- 16 Bit singleturn
- Data transfer up to 2 MBaud
- Optically isolated RS 422 interface
- Recessed hollow shaft
- Zero-set function

Function

This singleturn absolute encoder with modern fast technology transmits a position value corresponding to the shaft setting via the SSI interface (Synchronous Serial Interface). The resolution of the ASS58 is maximum 65536 steps per revolution. The devices of the ASS58 series are equipped with a microcontroller. The control module sends a clock bundle to the absolute encoder to obtain position data. The rotary encoder then sends the position data synchronous to the cycles of the control module. It is possible to select the following items with function inputs the counting direction and the zero-set function (preset value). The absolute encoder is mounted directly onto the application shaft, without any coupling. Rotation of the absolute encoder is prevented by a torque rest. The electrical connection is made by a 12-pin round plug connector. It is also possible to obtain a version with a 1 m cable connector.

Interface

Description

The Synchronous Serial Interface was specially developed for transferring the output data of an absolute encoder to a control device. The control module sends a clock bundle and the absolute encoder responds with the position value. Thus only 4 lines are required for the clock and data, no matter what the resolution of the rotary encoder is. The RS 422 interface is optically isolated from the power supply.

SSI signal course Standard

- | | | | |
|--|-----------------------|------------------|--|
| D ₁ , ..., D _n : | Position data | T = 1/f: | Duration of period of clock signal ≤ 1 MHz |
| S: | Special bit | T _m : | Monoflop time 10 μs ... 30 μs |
| MSB: | Most significant bit | T _p : | Clock pause ≥ monoflop time (T _p ≥ T _m) |
| LSB: | Least significant bit | | |

SSI output format Standard

- At idle status signal lines "Data +" and "Clock +" are at high level (5 V).
- The first time the clock signal switches from high to low, the data transfer in which the current information (position data (D_n) and special bit (S)) is stored in the encoder is introduced.
- The highest order bit (MSB) is applied to the serial data output of the encoder with the first rising pulse edge.
- The next successive lower order bit is transferred with each following rising pulse edge.
- After the lowest order bit (LSB) has been transferred the data line switches to low until the monoflop time T_m has expired.
- No subsequent data transfer can be started until the data line switches to high again or the time for the clock pause T_p has expired.
- After the clock sequence is complete, the monoflop time T_m is triggered with the last falling pulse edge.
- The monoflop time T_m determines the lowest transmission frequency.

SSI output format ring slide operation (multiple transmission)

- In ring slide operation, multiple transmission of the same data word over the SSI interface makes it possible to offer the possibility of detecting transmission errors.
- In multiple transmission, 25 bits are transferred per data word in standard format.

Release date: 2023-02-14 Date of issue: 2023-02-14 Filename: t49170_eng.pdf

- If the clock change is not interrupted after the last falling pulse edge, ring slide operation automatically becomes active. This means that the information that was stored at the time of the first clock change is generated again.
- After the first transmission, the 26th pulse controls data repetition. If the 26th pulse follows after an amount of time greater than the monoflop time T_m , a new current data word will be transmitted with the following pulses.

If the pulse line is exchanged, the data word is generated offset. Ring slide operation is possible up to max. 13 bits.
